

Trading conduct report 27 July – 2 August 2025

Market monitoring weekly report

Trading conduct report 27 July – 2 August 2025

1. Overview

1.1. This week the average national spot price decreased by \$42/MWh this week to \$119/MWh. Demand decreased also due to mild temperatures. Thermal generation also declined, with only Huntly 5 running as baseload. National hydro storage remains stable at ~59% nominally full and ~95% of the historical average. The new hybrid/forecasting/arrangement began on 31 July.

2. Spot prices

- 2.1. This report monitors underlying wholesale price drivers to assess whether trading periods require further analysis to identify potential non-compliance with the trading conduct rule. In addition to general monitoring, it also singles out unusually high-priced individual trading periods for further analysis by identifying when wholesale electricity spot prices are outliers compared to historic prices for the same time of year.
- 2.2. Between 27 July 2 August 2025:
 - (a) The average spot price for the week was \$119/MWh, a decrease of around \$42/MWh compared to the previous week.
 - (b) 95% of prices fell between \$42/MWh and \$205/MWh.
- 2.3. Spot prices were mostly under \$200/MWh with a few price spikes. On Wednesday, prices were low, likely due to relatively low demand. Spot prices were elevated from Friday due to lower wind and resulted in higher priced hydro generation dispatched.
- 2.4. The highest price of the week occurred during the evening peak on Tuesday between 5.30pm-6.30pm, with a maximum of ~\$287/MWh at Ōtāhuhu and ~\$238/MWh at Benmore. During these times, demand was higher than forecast by 4MW-54MW and wind was 103MW-146MW lower than forecast.
- 2.5. Another significant price spike occurred at 2.00am on Saturday, with prices reaching around \$216/MWh at Ōtāhuhu and \$223/MWh at Benmore. At this time, wind was low and hydro generation was higher than usual for an overnight period, wind generation was underestimated by 55MW.
- 2.6. Figure 1 shows the wholesale spot prices at Benmore and Ōtāhuhu alongside the national historic median and historic 10-90th percentiles adjusted for inflation. Prices greater than quartile 3 (75th percentile) plus 1.5 times the inter-quartile range of historic prices, plus the difference between this week's median and the historic median, are highlighted with a vertical black line. Other notable prices above \$250/MWh are marked with black dashed lines.

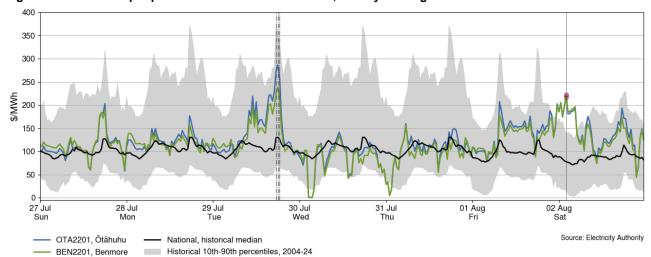

Figure 1: Wholesale spot prices at Benmore and Ōtāhuhu, 27 July - 2 August 2025

- 2.7. Figure 2 shows a box plot with the distribution of spot prices during this week and the previous nine weeks. The yellow line shows each week's median price, while the blue box shows the lower and upper quartiles (where 50% of prices fell). The 'whiskers' extend to points that lie within 1.5 times of the interquartile range (IQR) of the lower and upper quartile. Observations that fall outside this range are displayed independently.
- 2.8. The distribution of spot prices this week was narrower than last week, with no significant high-priced outliers. The median price was \$114/MWh and most prices (middle 50%) fell between \$99/MWh and \$137/MWh.

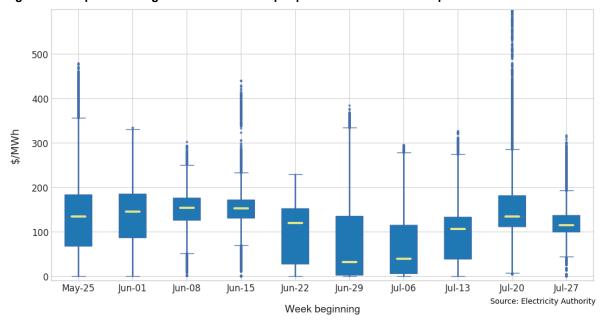

Figure 2: Box plot showing the distribution of spot prices this week and the previous nine weeks

3. Reserve prices

3.1. Fast instantaneous reserve (FIR) prices for the North and South Islands are shown below in Figure 3. FIR prices were mostly below \$5/MWh with a few spikes. Significant FIR price spikes occurred on Thursday at 8.30pm, with prices reaching around \$55/MWh in the North

Island and \$41/MWh in the South Island. At this time Huntly 5 was the risk setter and there was a reduction in the quantity of tail-water-depressed FIR offered into the market.

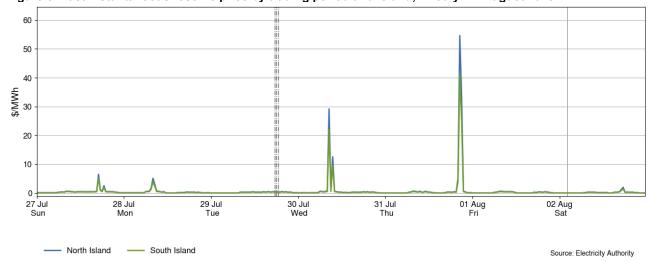

Figure 3: Fast instantaneous reserve price by trading period and island, 27 July - 2 August 2025

3.2. Sustained instantaneous reserve (SIR) prices for the North and South Islands are shown in Figure 4. SIR prices were mostly below \$5/MWh with a few spikes. The highest SIR price was also at 8.30pm on Thursday with prices of \$27/MWh in the North Island and \$25/MWh in the South Island. At this time, Huntly 5 was the risk setter. In general when thermal commitment is low there is an overall reduction in reserve available, and reserve prices can spike when higher amounts of reserve are required.

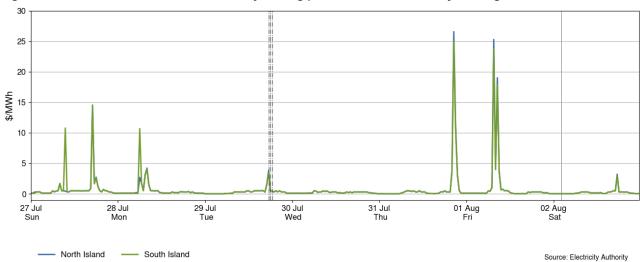

Figure 4: Sustained instantaneous reserve by trading period and island, 27 July - 2 August 2025

4. Regression residuals

4.1. The Authority's monitoring team uses a regression model to model electricity spot prices. The residuals show how close predicted spot prices were to actual prices. Large residuals may indicate that prices do not reflect underlying supply and demand conditions. Details on the regression model and residuals can be found in <u>Appendix A</u>.

- 4.2. Figure 5 shows the residuals of autoregressive moving average (ARMA) errors from the daily model. Positive residuals indicate that the modelled daily price is lower than the actual average daily price and vice versa. When residuals are small this indicates that average daily prices are likely largely aligned with market conditions. These small deviations reflect market variations that may not be controlled in the regression analysis.
- 4.3. This week, there were no residuals above or below two standard deviations, indicating that prices were similar to those predicted by the model.

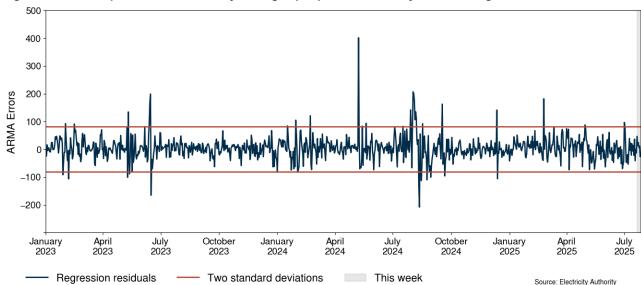

Figure 5: Residual plot of estimated daily average spot prices, 1 January 2023 - 2 August 2025

5. **HVDC**

5.1. Figure 6 shows the HVDC flow between 27 July – 2 August 2025. HVDC flows were mostly northward during the day and southward overnight. On Saturday, there wasn't any southward flow due to low wind generation. Northward flows reached around 698MW on Saturday at 6.00pm. Northward flow was also high (up to 681MW) on Tuesday during the price spikes.

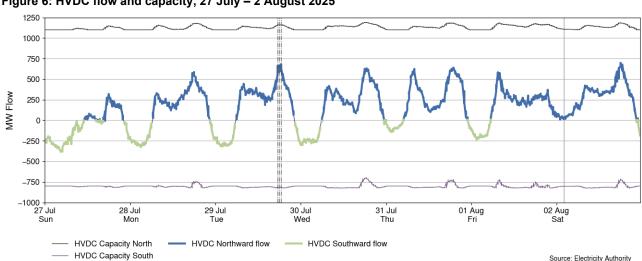

Figure 6: HVDC flow and capacity, 27 July - 2 August 2025

6. Demand

6.1. Figure 7 shows national demand between 27 July – 2 August 2025, compared to the historic range and the demand of the previous week. Overall, demand was lower this week compared to the previous week due to mild temperatures. The highest demand of the week was 3.2GWh at 5.30pm on Tuesday.

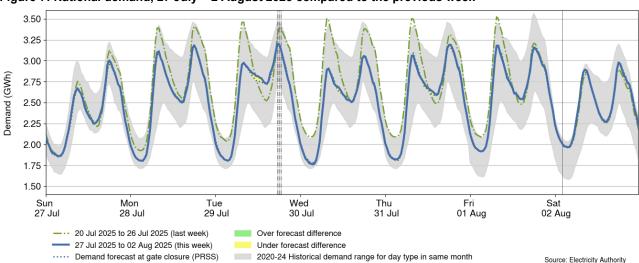

Figure 7: National demand, 27 July - 2 August 2025 compared to the previous week

- 6.2. Figure 8 shows the hourly apparent temperature at main population centres from 27 July 2 August 2025. The apparent temperature is an adjustment of the recorded temperature that accounts for factors like wind speed and humidity to estimate how cold it feels. Also included for reference is the mean temperature of the main population centres, and the mean historical apparent temperature of similar weeks, from previous years, averaged across the three main population centres.
- 6.3. Apparent temperatures ranged from 3°C to 15°C in Auckland, 0°C to 12°C in Wellington, and -8°C to 11°C in Christchurch. Christchurch experienced freezing mornings on Sunday, Monday, and Saturday. From Monday to Thursday, mild temperatures contributed to reduced demand.

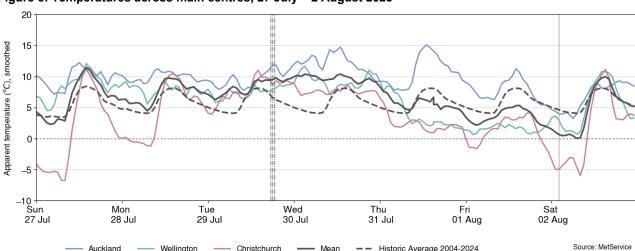

Figure 8: Temperatures across main centres, 27 July - 2 August 2025

7. Generation

7.1. Figure 9 shows wind generation and forecast from 27 July – 2 August 2025. This week wind generation varied between 110MW and 827MW, with a weekly average of 427MW. Wind generation was mostly below 600MW. During Tuesday's price spike, wind was 103MW-146MW lower than expected. The new https://example.com/hybrid/forecasting/arrangement began on 31 July.

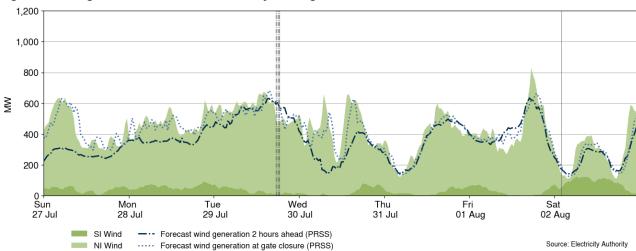

Figure 9: Wind generation and forecast, 27 July – 2 August 2025

7.2. Figure 10 shows grid connected solar generation from 27 July – 2 August 2025. Solar generation was lowest on Tuesday. Except for Tuesday, solar generation typically peaked above 50MW, with a maximum of 98MW at 10.30am on Sunday.

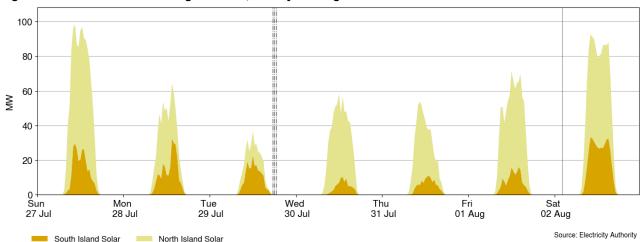

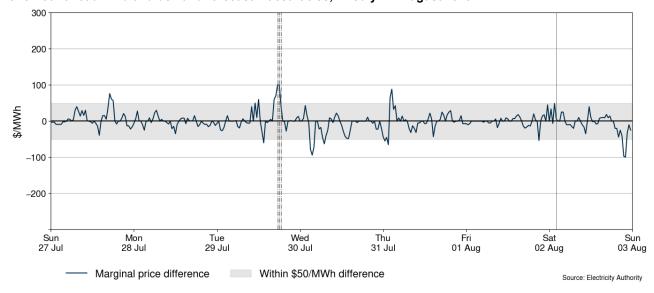

Figure 10: Grid connected solar generation, 27 July - 2 August 2025

7.3. Figure 11 shows the difference between the national real-time dispatch (RTD) marginal price and a simulated marginal price where the real-time wind and demand matched the 1-hour ahead forecast (PRSS¹) projections. The figure highlights when forecasting inaccuracies are causing large differences to final prices. When the difference is positive this means that the 1-hour ahead forecasting inaccuracies resulted in the spot price being higher than anticipated - usually here demand is under forecast and/or wind is over forecast. When the difference is negative, the opposite is true. Because of the nature of

¹ Price responsive schedule short – short schedules are produced every 30 minutes and produce forecasts for the next 4 hours.

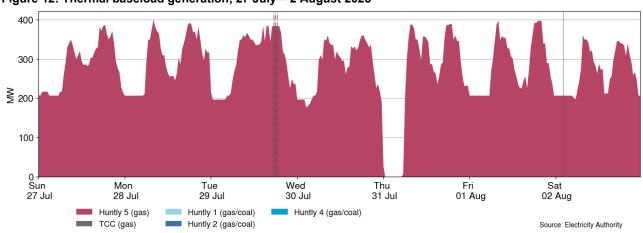

- demand and wind forecasting, the 1-hour ahead and the RTD wind and demand forecasts will rarely be the same. Trading periods where this difference is exceptionally large can signal that forecasting inaccuracies had a large impact on the final price for that trading period.
- 7.4. A few trading periods this week had positive marginal price differences above \$50/MWh which were driven by wind and demand forecasting errors. The largest positive price difference of +\$100/MWh occurred during the price spike at 6.00pm on Tuesday, when wind was 146MW lower than forecast.

Figure 11: Difference between national marginal RTD price and simulated RTD price, with the difference due to one-hour ahead wind and demand forecast inaccuracies, 27 July – 2 August 2025

7.5. Figure 12 shows the generation of thermal baseload between 27 July – 2 August 2025. Huntly 5 ran as baseload throughout the week, except on Thursday night.

Figure 12: Thermal baseload generation, 27 July – 2 August 2025

7.6. Figure 13 shows the generation of thermal peaker plants between 27 July – 2 August 2025. Stratford Peaker 2 ran on Sunday and Monday. Junction Road generated throughout the week during peak periods. Huntly Unit 6 ran daily during the evening peak and continuously from Thursday night to Friday night.

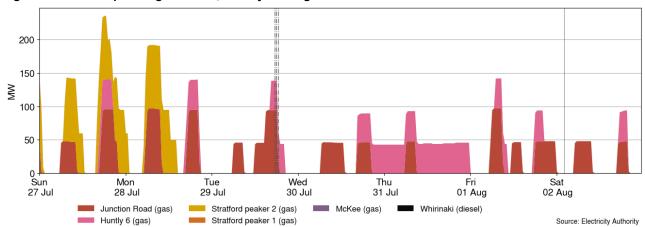

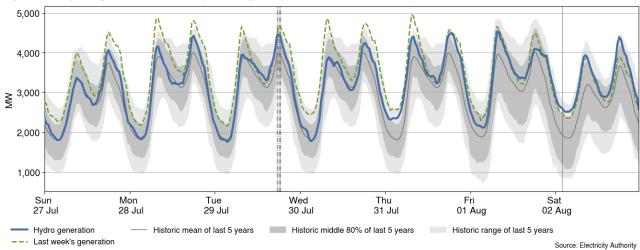

Figure 13: Thermal peaker generation, 27 July - 2 August 2025

7.7. Figure 14 shows hydro generation between 27 July – 2 August 2025. Hydro generation decreased compared to the previous week due to relatively lower demand. On Tuesday, during the price spike, hydro generation increased to meet demand.

7.8. As a percentage of total generation, between 27 July – 2 August 2025, total weekly hydro generation was 61.9%, geothermal 21.8%, wind 8.2%, thermal 6.3%, co-generation 1.4%, and solar (grid connected) 0.3%, as shown in Figure 15.

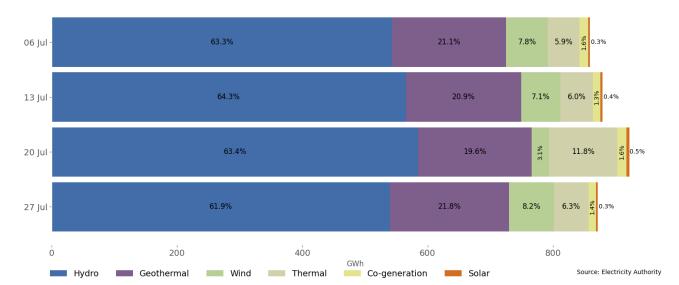

Figure 15: Total generation by type as a percentage each week, between 6 July - 2 August 2025

8. Outages

- 8.1. Figure 16 shows generation capacity on outage. Total capacity on outage between 27 July 2 August 2025 ranged between ~589MW and ~1,330MW. Figure 17 shows the thermal generation capacity outages.
- 8.2. Notable outages include:
 - (a) Stratford peaker 1 is on outage until 10 August 2025.
 - (b) Manapōuri unit 4 is on outage until 12 June 2026.
 - (c) Manapōuri unit 2 was on outage between 26-29 July 2025.

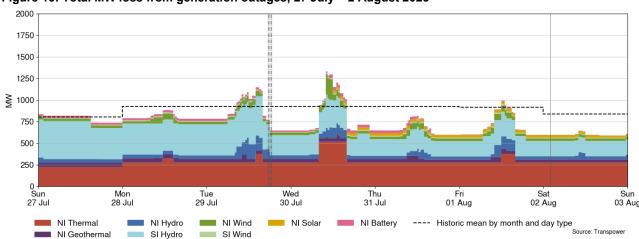

Figure 16: Total MW loss from generation outages, 27 July – 2 August 2025

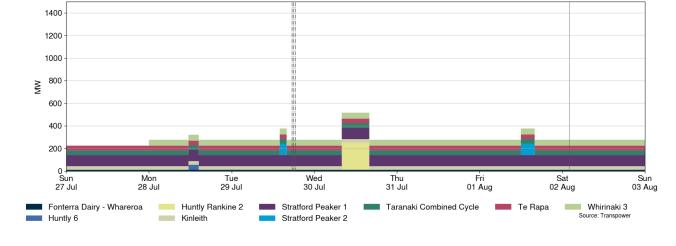

Figure 17: Total MW loss from thermal outages, 27 July - 2 August 2025

9. Generation balance residuals

- 9.1. Figure 18 shows the national generation balance residuals between 27 July 2 August 2025. A residual is the difference between total energy supply and total energy demand for each trading period. The red dashed line represents the 200MW residual mark which is the threshold at which Transpower issues a customer advice notice (CAN) for a low residual situation. The green dashed line represents the forecast residuals and the blue line represents the real-time dispatch (RTD) residuals.
- 9.2. Residuals were healthy this week. The lowest national residual was 566MW on Tuesday at 5.30pm.

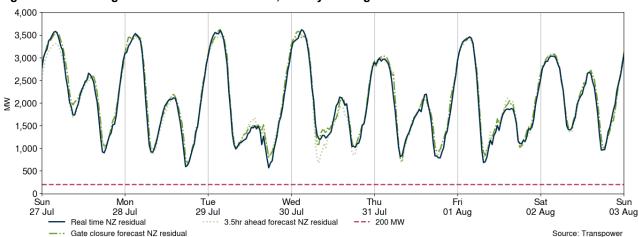

Figure 18: National generation balance residuals, 27 July - 2 August 2025

10. Storage/fuel supply

- 10.1. Figure 19 shows the total controlled national hydro storage as well as the storage of major catchment lakes including their historical mean and 10th to 90th percentiles.
- 10.2. As of 2 August 2025, national controlled hydro storage remains stable at 59% of nominal full and ~95% of the historical average for this time of the year.

- 10.3. Storage at Lake Pūkaki (53% full²) is below its historical average, and storage at Lake Takapō (40% full) is between its historic mean and 10th percentile.
- 10.4. Storage at Lake Te Anau (44% full) and Lake Manapōuri (43% full) is currently below their respective historical mean.
- 10.5. Storage at Lake Taupō (78% full) is touching its historical 90th percentile.
- 10.6. Storage at Lake Hawea (40% full) remains between its historical 10th percentile and mean.

² Percentage full values sourced from NZX hydrological summary 3 August 2025.

11. Prices versus estimated costs

01 Jun 2025

01 Jul 2025

11.1. In a competitive market, prices should be close to (but not necessarily at) the short-run marginal cost (SRMC) of the marginal generator (where SRMC includes opportunity cost).

01 Aug 2025

100

01 May 2025

01 Jun 2025

60

01 May 2025

- 11.2. The SRMC (excluding opportunity cost of storage) for thermal fuels is estimated using gas and coal prices, and the average heat rates for each thermal unit. Note that the SRMC calculations include the carbon price, an estimate of operational and maintenance costs, and transport for coal.
- 11.3. Figure 20 shows an estimate of thermal SRMCs as a monthly average up to 1 July 2025. The SRMCs for gas powered generation have decreased, while the SRMC for diesel fuelled generation slightly increased.
- 11.4. The latest SRMC of coal-fuelled Rankine generation is ~\$150/MWh. The cost of running the Rankines on gas is ~\$159/MWh.
- 11.5. The SRMCs of gas fuelled thermal plants are currently between \$106/MWh and \$159/MWh.
- 11.6. The SRMC of Whirinaki is ~\$513/MWh.
- 11.7. More information on how the SRMC of thermal plants is calculated can be found in Appendix C.

Figure 20: Estimated monthly SRMC for thermal fuels

12. Offer behaviour

- 12.1. Figure 21 shows this week's national daily offer stacks. The black line shows cleared energy, indicating the range of the average final price.
- 12.2. This week most offers cleared in the \$100-\$200/MWh range. On Tuesday, during a few trading periods in the evening peak period, high demand and demand forecast errors caused energy to clear into higher price band.
- 12.3. On Saturday night, energy from the highest price of \$200-\$300/MWh band also cleared to meet demand.

Figure 21: Daily offer stacks

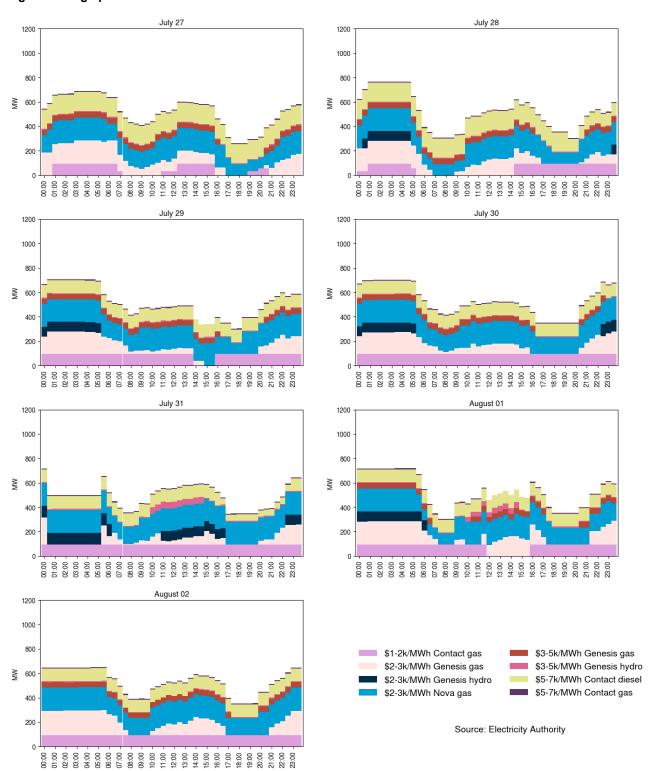

- 12.4. Figure 22 shows offers above \$1,000/MWh in each trading period this week. The largest proportion of these offers are fast start thermal operators.
- 12.5. If forecast prices are lower than thermal operating costs, this signals some generators may not be needed in that half-hourly trading period. Thermal generators may then price their units high, as they aren't expecting to run. These high prices reflect increased operating

costs of running for only a short time. So, if demand is unexpectedly high, wind generation dips, or other generation fails, these high-priced thermal generators may get dispatched, sometimes resulting in a high spot price.

12.6. On average 519MW per trading period was priced above \$1,000/MWh this week, which is roughly 8.9% of the total energy available.

Figure 22: High priced offers

13. Ongoing work in trading conduct

- 13.1. This week prices generally appeared to be consistent with supply and demand conditions. The monitoring team is analysing Waikato offer pricing changes this week.
- 13.2. Further analysis is being done on the trading periods in Table 1 as indicated.

Table 1: Trading periods identified for further analysis

Date	Trading period	Status	Participant	Location	Enquiry topic
22/09/2023- 30/09/2023	Several	Back with monitoring for analysis	Contact	Multiple	High hydro offers
